How it works:
app/Controllers
Controller needs to be named in this pattern: [CONTROLLER_NAME]Controller.php

app/Views
That the framework can load the View fort he Controller and Action there must be an Directory called like the Controller example: app/Views/User, when Controller is called UserController. For example if the action is Login the Framework will search after Login.php in app/Views/User.

URL's in Browser: User&action=Login or User&action=getUser&param=20 will work but User/Login or User/getUser/20 will not work.

app/Models
Add models here

core/Helper.php

Use this class for helper methods

database/

Use this directory to add the exported files from the Database to keep track of the different DB versions.

Styles/

All CSS things

If you want you can create any other directory in the root directory for whatever else you would need to use. (js, ajax, libraries, docs etc.)
